Which Comes First, Calving or Rebreeding?

Preparation for calving is often first priority, but don’t leave rebreeding as an afterthought.

by Chad Zehnder

Mature cows should calve in at a minimum of 5.5 BCS, but preferably at a score of 6. Heifers should calve at a minimum score of 6. Supplementation can help maintain a consistent BCS which can lead to cows breeding back quickly, optimized conception rates and heavier calf weaning weights.

2) Evaluate your mineral program

Mineral nutrition is one of the most commonly overlooked items on the calving and rebreeding preparation list. “We tend to think about the importance of minerals either right at calving or before breeding, but we need to make sure we’re providing an adequate mineral program year-round,” Zehnder says. “Minerals are especially important 60 to 90 days before calving, since they impact colostrum quality, calf trace mineral status and calf health.”

Minerals also play a role in tissue repair, helping the cow’s reproductive tract repair from calving and prepare for breeding. If the tract is not fully repaired, a cow may have challenges being rebred or she may not breed back at all.

A program with highly bioavailable trace mineral sources can be of benefit, especially leading up to calving season and through breeding. The bioavailability of a mineral source alters the absorptive ability of the trace minerals eliciting their full benefit.

3) Discuss herd health with your veterinarian

If you do not have a comprehensive herd health program, now is the time to talk with your veterinarian or animal health supplier to develop one. If you have a program, it can be beneficial to re-evaluate and ensure the protocols still make sense. “Make sure you have a vaccination program in place for both cows and calves,” Zehnder says. “Since every operation has a different risk level in how and when they calve, the program should be specific to your operation and region.”

For operations with multiple employees, make sure everyone is familiar and comfortable with the program ahead of time. Getting everyone on the same page before calving begins can help ensure protocols are followed correctly and consistently.

4) Take time to troubleshoot

Calving and rebreeding are two of the most important events for an operation’s bottom line which makes it stressful when things don’t go as planned. However, an overreaction may make things even worse.

“It’s easy to get frustrated when there’s a bump in the road, but it’s important to take an objective approach when a challenge arises,” Zehnder says. “Troubleshoot and try to figure out what the true cause is versus making a knee-jerk decision.”

Involving your nutritionist, veterinarian, suppliers, employees and other key personnel to help work through a cause and solution. A team discussion can help identify the diagnostic work needed to find a solution.

Regardless of which takes priority in your mind, calving and rebreeding success is always in season. “We need to think about that critical 85-day window year-round. Every management decision we make throughout the year should focus on a cow delivering a live, healthy calf and being rebred back in that time frame,” Zehnder says. HM
